

MALNUTRITION : INTERET DE LA CALORIMETRIE INDIRECTE

Pr M. FAROUDY

*Réanimation des Urgences Chirurgicales
CHU Ibn Sina*

Rabat - Maroc

INTRODUCTION

- ❑ Nutrition = indispensable au support des fonctions vitales
- ❑ La malnutrition est fréquente, méconnue
- ❑ Sous nutrition et surnutrition = morbi-mortalité

- ❑ Evaluation de la dépense énergétique : base de prescription.
- ❑ Limites des équations prédictives
- ❑ Calorimétrie indirecte :
 - Précise, reproductible
 - Peu disponible (investissement, complexité)

INTERETS DU MONITORAGE DU METABOLISME EN REANIMATION

Adaptation des apports caloriques

Adaptation de la ventilation

Suivi et prédiction du sevrage par la VO₂

Mesure de l'espace mort

Mesure de la CRF

Détermination de la “best” PEEP

Evaluation du volume recruté

NUTRITION DISORDERS

Nutrition disorders and nutrition related conditions

Malnutrition/
Undernutrition

Sarcopenia
and Frailty

Overweight
and Obesity

Micronutrient
abnormalities

Re-feeding
syndrome

DEFINITION

Malnutrition

“a state resulting from **lack of intake or uptake** of nutrition that leads to**altered body composition** (decreased fat free mass and body cell mass) leading to **diminished physical and mental function** and impaired clinical outcome from disease”¹

CAUSES DE DÉNUTRITION

Déficit d'apport énergétique, protéique et en micronutriments

- Régime pauvre
- Anorexie
- Jeûne pour bilan ou intervention...
- Douleur
- Nausées
- Dysphagie
- Dépression
- Incapacité de se nourrir
- Troubles de conscience

CAUSES DE DÉNUTRITION

Altération fonctionnelle (tube digestif, foie...)

- Iléus réflexe
- Choc
- Douleur, sédation

Pertes digestives

- Vomissements
- Sonde gastrique
- Diarrhées, grêle court
- Drains chirurgicaux
- Fistules
- Stomies

CAUSES DE DÉNUTRITION

Réponse hypercatabolique

- Inflammation
- Cancer
- Trauma
- Brûlures

VARIATION DES BESOINS MÉTABOLIQUES

Selon la pathologie

Dans le temps

IN THE ICU

- ❑ Age usually older
- ❑ Acute illness ,hypercatabolic state.
- ❑ Coexisting chronic diseases
- ❑ Mechanical ventilation
- ❑ Haemodynamic instability from the 1ry insult
- ❑ Interruptions of meal times
- ❑ Nutrition is not a priority issue????

CONSEQUENCES DE L'INADEQUATION DES APPORTS

Effects of overfeeding and underfeeding.

	Insufficient energy intake	Excessive energy intake
Early signs	Hypoglycemia Hypothermia	Hyperglycemia Hyperlipidemia (triglycerides) Hypercapnea
Delayed signs	Infectious complications Impaired immunity Impaired healing Loss of lean and fat body mass Impaired muscle function	Infectious complications Impaired immunity Liver steatosis Increased fat mass

Perte tissulaire : diminution de la masse
maigre, 2 % par jour (fonte musculaire)

Difficulté de sevrage de la ventilation mécanique.
Augmentation de la durée de séjour en réanimation et à l'hôpital

Effectiveness of intensive nutritional regimes in patients who fail to wean from mechanical ventilation

Larca L., 01 May 1982

2-year period, 14 ventilator-dependent patients

- group 1 (N = 6) did not wean from MV, died in the hospital
- group 2 (N = 8) weaned from M, eventually discharged.

the two groups did not differ with regard to serum albumin or transferrin levels, or in total lymphocyte count.

After the period of aggressive nutritional support, group 2 patients showed an increase in serum albumin and transferrin whereas patients in group 1 showed a decrease.

The lymphocyte count did not change significantly.

Ventilator-dependent patients who respond to nutritional support with an increase in protein synthesis are more likely to wean from mechanical ventilation than those who do not.

MALNUTRITION ET MORTALITE

- ❑ 3,122 patients, 56 hospitals, Australia and New Zealand
- ❑ 32% malnourished
- ❑ Odds of 90 day in hospital mortality twice greater

il est admis que la dénutrition augmente la mortalité en réanimation, à l'hôpital et à six mois

Nutrition artificielle en réanimation

RECOMMANDATIONS FORMALISÉES D'EXPERTS

Annales Françaises d'Anesthésie et de Réanimation 33 (2014)

BMI, AGE ET MORTALITE

Figure 1. Predicted probability of death as a function of body mass index (BMI) calculated from the logistic model for each of 5 age groups. The plotted points are mean values for subjects in a given weight group. Highest mortality almost always occurs at lowest BMI and mortality also increases at greatest BMI.

being underweight is a more potent threat to life than obesity

The relationship between nutritional intake and clinical outcomes in critically ill patients: results of an international multicenter observational study.

Alberda, et al. *Int Care Med.* 2009;35:1821.

EN (69% of patients), TPN (8%), EN+SPN (17.6%), none (5.4%).

COUT DE LA DENUTRITION

hospital costs were increased by 60.5% in malnourished patients compared with well-nourished patients...

...and by 308.9% when the costs for medications and tests were included

Durée de séjour
Durée de VM
Complications

Correia M, et al. *Clin Nutr.* 2003;22:235-239.

COUT DE LA NUTRITION

La nutrition parentérale est plus coûteuse que l'entérale

VS

Les coûts indirects sont à prendre en compte

QUE FAIRE ?

Encadré 3.1 – Il faut probablement évaluer l'état nutritionnel des patients à l'admission au minimum en calculant l'IMC et en évaluant la perte de poids ([Accord faible](#)).

Nutrition Day ICU: A 7 year worldwide prevalence study of nutrition practice in

August 2016

9777 patients of 880 units from 46 countries ...

...this study shows that most of the ICU patients are fed enterally, that enteral feeding is started after a median of 1 day ...

...the **nutritional target is rarely reached**, if ever after 5 days... most surprisingly there appears to be no adaptation of energy intake to body weight as it is generally recommended.

ESTIMATION DE LA DEPENSE ENERGETIQUE PAR EQUATIONS

Harris Benedict (basic):

Men: $13.75(\text{wt}) + 5(\text{ht}) - 6.8(\text{age}) + 66$

Women: $9.6(\text{wt}) + 1.8(\text{ht}) - 4.7(\text{age}) + 655$

Harris Benedict (variants): HBEa(25) substitutes adjusted body weight in obese patients calculated as

$(\text{Actual wt} - \text{ideal wt}^b)0.25 + \text{ideal wt}$

HBEa(25) $\times 1.25$ uses the HBEa(25) value and multiplies it by a 1.25 stress factor

HBEa(50) substitutes adjusted body weight in obese patients calculated as $(\text{adjusted wt} - \text{ideal wt}^b)0.50 + \text{ideal wt}$

HBEa(50) $\times 1.25$ uses the HBEa(50) value and multiplies it by a 1.25 stress factor

Poids / Taille / Age

Mifflin St. Jeor:

Men: $10(\text{wt}) + 6.25(\text{ht}) - 5(\text{age}) + 5$

Women: $10(\text{wt}) + 6.25(\text{ht}) - 5(\text{age}) - 161$

American College of Chest Physicians (ACCP):

25kcal/kg (actual wt in obese subjects)

25 kcal/kg (adjusted wt in obese subjects)

+ FR / VT

Swinamer: $\text{BSA}(941) - \text{Age}(6.3) + \text{T}(104)^c + \text{RR}(24)^c + \text{Vt}(804)^c - 4243$

Ireton-Jones: $\text{Wt}(5) - \text{Age}(10) + \text{Male}(281) + \text{Trauma}(292) + \text{Burn}(851)$

Brandi: $\text{HBE}(0.96) + \text{HR}(7)^c + \text{Ve}(48)^c - 702$

Sexe/Trauma/Brûlure

Penn State:

$\text{PSU}(\text{HBE}) = \text{HBE}(0.85) + \text{Tmax}(175)^d + \text{Ve}(33)^d - 6344$

$\text{PSU}(\text{HBEa}) = \text{HBEa}(1.1) + \text{Tmax}(140)^d + \text{Ve}(32)^d - 5340$

$\text{PSU}(\text{m}) = \text{Mifflin}(0.96) + \text{Tmax}(167)^d + \text{Ve}(31)^d - 6212$

Faisy: $\text{Wt}(8) + \text{Ht}(14) + \text{Ve}(32)^c + \text{T}(94)^c - 4834$

+ Temp / VM

Analysis of Estimation Methods for Resting Metabolic Rate in Critically Ill Adults

David C. Frankenfield, Abigail Coleman, Shoaib Alam and Robert N. Cooney

Journal of Parenteral and Enteral

202 ventilated, adult
critical care patients

resting metabolic rate

Standardized
indirect
calorimetry

VS

Harris Benedict
Mifflin
Penn State equation,
Faisy
Brandi
Swinamer
Ireton-Jones

- Accuracy.. 67% for the Penn State equation to 18% for the weight-adjusted Harris Benedict equation
- Within subgroups...highest accuracy rate was 77% in the elderly nonobese using the Penn State equation and the lowest was 0% for the weight-adjusted Harris Benedict equation.
- The Penn State equation was the only equation that was unbiased and precise across all subgroups.
- The obese elderly group was the most difficult to predict.

NUTRITION: RECOMMANDATIONS

Annales Françaises d'Anesthésie et de Réanimation 33 (2014) 202–218

RECOMMANDATIONS FORMALISÉES D'EXPERTS

2014

Nutrition artificielle en réanimation

Guidelines for nutrition support in critically ill patient

J.-Y. Lefrant^{a,*}, D. Hurel^b, N.J. Cano^{c,d,e}, C. Ichai^f, J.-C. Preiser^g, F. Tamion^h

^a Services des réanimations, division anesthésie réanimation douleur urgence, CHU de Nîmes, place du Pr-Robert-Debré, 30029 Nîmes cedex 9, France

Encadré 1.1 – Tout patient admis en réanimation pour une durée présumée supérieure à 3 jours est à risque de dénutrition. Cette dernière augmente la morbi-mortalité (infection en particulier) et les durées de ventilation, de séjour et d'hospitalisation (Accord fort).

Encadré 2.1 – Pour évaluer précisément la dépense énergétique d'un patient de réanimation, il faut utiliser la calorimétrie indirecte (méthode de référence en tenant compte de ses limites d'utilisation) plutôt que les équations prédictives (Accord faible).

Encadré 4.5 – En cas d'utilisation de calorimétrie indirecte, il ne faut probablement pas dépasser la dépense énergétique mesurée (Accord faible).

Encadré 9.6.3 – En tenant compte de ce poids ajusté, il faut probablement apporter 20 kcal/kg par jour dont 2 g/kg par jour de protéines (Accord faible).

Metabolic and nutritional support of critically ill patients: consensus and controversies

Table 2 Areas of consensus (ICU patients with a more than 4-day length of stay)

	Consensus
Early enteral feeding	Consider in each patient without absolute contraindication; prevents mucosal atrophy
Risks of overfeeding	Early phase
Estimation of energy expenditure	Requires indirect calorimetry – cannot be predicted by equations
Arginine	Not recommended in sepsis; beneficial in perioperative patients outside the ICU
Vitamins, trace elements	Mandatory, in nutritional doses; particularly true in parenteral nutrition

Moreover, predictive equations are not sufficiently accurate for reliable use in critically ill patients [28]. Nevertheless, measurement of EE is feasible using indirect calorimetry, and guidelines from both the European Society for Clinical Nutrition and Metabolism [41] and the American Society for Parenteral and Enteral Nutrition [42] recommend use of this technique,

Calorimétrie indirecte pour les patients qui doivent séjourner en réanimation

CALORIMÉTRIE

PRINCIPE DE MESURE

Mesure/calcul continu de fiO_2 , feO_2 , feCO_2 , fiCO_2 et VM

The diagram illustrates the calculation of oxygen consumption (VO_2). It shows two vertical rectangles. The first rectangle on the left is divided into a large blue top section and a smaller red bottom section. Below it is the label $\text{VMinsp} \times \text{fiO}_2$. A minus sign is between the two rectangles. The second rectangle is also divided into a large blue top section and a smaller red bottom section. Below it is the label $\text{VMexp} \times \text{feO}_2$. An equals sign follows, leading to a single red rectangle. Below it is the label VO_2 .

$$\text{VMinsp} \times \text{fiO}_2 - \text{VMexp} \times \text{feO}_2 = \text{VO}_2$$

Consommation
d'oxygène VO_2 [ml/
min]

The diagram illustrates the calculation of carbon dioxide production (VCO_2). It shows two vertical rectangles. The first rectangle on the left is divided into a large blue top section and a smaller green bottom section. Below it is the label $\text{VMexp} \times \text{feCO}_2$. A minus sign is between the two rectangles. The second rectangle is entirely blue. Below it is the label $\text{VMinsp} \times \text{fiCO}_2$. An equals sign follows, leading to a single green rectangle. Below it is the label VCO_2 .

$$\text{VMexp} \times \text{feCO}_2 - \text{VMinsp} \times \text{fiCO}_2 = \text{VCO}_2$$

Production de CO_2
 VCO_2 [ml/min]

CALORIMÉTRIE INDIRECTE

PARAMETRES CALCULES

Consommation Energétique

$$CE = 5.5 VO_2 + 1.76 VCO_2 - 1,99UN \quad (\text{en Kcal/jour})$$

UN = Azote Urinaire (N2) quotidien produit

*A défaut de valeur personnalisée: UN = 13 g/jour

Weir's equation

$$EE = [(VO_2 \times 3.941) + (VCO_2 \times 1.11) + (u N_2 \times 2.17)] \times 1.44$$

REE = Rest Energy Expenditure – Consommation énergétique de repos/24h
(en L/jour pour les gaz, g/jour pour les substrats oxydés)

Calculés en continu

Quotient Respiratoire

$$RQ = VCO_2/VO_2$$

Respiratory Quotient = Respiratory Exchange Ratio

The screenshot shows the 'Energy Requirement Evaluation' window from GE. It includes fields for Date (12/07/06) and Patient (N° 4362 Ms A.G.). The Harris-Benedict Method section has radio buttons for Gender (Male selected) and Height (inches selected). It also has fields for Age (66), Height (175), Weight (74), REE (1512.8), Percent Adjustment (3), and Adjusted REE (1557.4). The Indirect Calorimetry Method section has fields for VD2 (153), VCO2 (128), Urinary nitrogen (13), and REE (1043.7). At the bottom, there is a 'Substrate use' section with fields for Carbohydrates (337.5), Fats (35.5), and Protein (81.2), each with a corresponding 'kcal/day' value.

Age	Height	Weight	REE (kcal/24 hr)	Percent Adjustment	Adjusted REE
66	175	74	1512.8	3	1557.4

VD2 (ml/min)	VCO2 (ml/min)	Urinary nitrogen (g/24hr)	REE (kcal/24 hr)
153	128	13	1043.7

Substrate	g/day	kcal/day
Carbohydrates	337.5	366.5
Fats	35.5	336.2
Protein	81.2	361

OPTIMISATION CALORIMÉTRIE INDIRECTE

Maximizing the chances of Steady State

- Mesures fiables Si/si état stable.
- Période de repos prolongé, stimuli patient minimaux
- Mêmes réglages de ventilation sur 1 ou 2 H (VT, FR, PEP, FiO₂)
- Pièges des modes assistés (FR variable, rapport I/E non imposé, trapping)

Les mesures doivent être prolongées
Les mesures doivent être répétées

LIMITES

bronchial suction
nursing interventions
patient activity.

- Physical agitation or unstable sedation and/or analgesia
- Air leaks (>10% of minute volume) Ballonnet, hautes pressions
- Unstable body temperature (> ± 1 °C change over last 1 h)
- Unstable pH (> ± 0.1 change over last 1 h)
- Oxygen enrichment ($\text{FiO}_2 > 60\%$)
- Organ support therapies: renal replacement or liver support therapy (pH alterations when conducted intermittently), ECMO (direct O_2 supply to the blood and CO_2 removal from the blood)

Seizures
involuntary movements

The higher the FiO_2 , the lower the VO_2 accuracy.

presence of N_2O .

Limitations due to Respiratory Gas Module Specifications

Breath rate > 35 bpm

Tidal Volume < 200 ml D-lite(+) or < 15 ml Pedi-lite(+)

CONCLUSION

- ❑ La mesure de dépense énergétique en réanimation est utile.
- ❑ Les calculs empiriques sont peu précis
- ❑ La calorimétrie indirecte reste peu utilisée en pratique clinique
- ❑ Son développement =
 - ❑ Optimisation des réglages de la ventilation
 - ❑ Prédicibilité du sevrage
 - ❑ Suivi continu des variations du métabolisme
 - ❑ Adaptation Apports / besoins nutritionnels
